## 1 Introduction

One of the most significant multi-day heatwaves on record affected southeast Australia over the period from 13 to 18 January 2014. A dome of very hot air developed over Western Australia in the second week of January, setting a number of records in that state, before moving eastwards to be over the southeast of the continent. A high-pressure system remained near-stationary over the Tasman Sea from the 13th onwards, directing mainly northerly winds over southeast Australia (including Tasmania), before a trough moved across the region on the 17th and 18th, bringing cooler air and ending the heatwave there.

The major area affected by the heatwave consisted of Victoria, Tasmania (particularly the western half), southern New South Wales away from the coast, and the southern half of South Australia. Over most parts of this region, it ranked alongside the heatwaves of January-February 2009, January 1939 and (from the limited information available) January 1908 as the most significant multi-day heatwaves on record. While peak temperatures mostly fell short of those observed in 2009 and 1939, extreme heat persisted for a longer period than it did in those heatwaves over some areas, particularly near-coastal regions of Victoria and South Australia (including Melbourne and Adelaide).

Numerous records were broken for extended periods of heat. Most notably, stateaverage data reveal that Victoria had its hottest four-day period on record, for both maximum and daily mean temperature. In both cases these surpassed records set in 2009, while for three-day periods the 2014 heatwave ranked second behind that of 2009. These two heatwaves, both of which have occurred in the last five years, stand ahead of any others recorded on a statewide basis. The heatwave was more notable for persistent heat than for individual extreme hot days, but some locations still had their hottest day on record, particularly in the southeast of South Australia, and around and to the west of the Snowy Mountains in New South Wales.

## 2 Detailed description of the heatwave

### 2.1 Evolution of the heatwave

Extreme heat initially developed in the Pilbara and Gascoyne regions of Western Australia from 8 January. Some very high temperatures occurred during this period, including $48.7^{\circ} \mathrm{C}$ at Onslow on 8 January, and $49.2^{\circ} \mathrm{C}$ at Emu Creek on 10 January. This heat moved south to cover much of the Southwest Land Division in Western Australia over the weekend of 11-12 January. Temperatures widely exceeded $45^{\circ} \mathrm{C}$ on one or both days of the weekend in the central and northern wheatbelt, and reached the low to mid 40s in coastal areas, including Perth, which also had its hottest night on record on 12 January.
Extreme heat moved into southeast Australia from 13 January onwards. Temperatures exceeded $40^{\circ} \mathrm{C}$ over much of South Australia and northern Victoria on the 13th, although seabreezes moderated conditions along parts of the coast. Winds across southeast Australia turned more northerly on the 14th, allowing extreme heat to extend to much of the Victorian coast. The 14th also saw the highest temperatures of the heatwave in parts of South Australia, and in western Tasmania.
The heat continued largely unabated over the southeast mainland (although less so in most of Tasmania) from the 15th to the 17th, and gradually extended northeastwards into southern inland New South Wales and the ACT. The most extreme heat finished on the 17th over South Australia and most of Victoria as a trough crossed both States, but very hot conditions continued into the 18th further north, in New South Wales and the far northeast of Victoria. Temperatures returned to near or below normal throughout the region from the 19th onwards.

### 2.2 The highest temperatures of the heatwave and notable site values

The highest absolute temperatures occurred in the initial phase of the event, in Western Australia. Emu Creek reached $49.2^{\circ} \mathrm{C}$ on 10 January, and Onslow $48.8^{\circ} \mathrm{C}$ on 8 January, while further south, Kellerberrin reached $47.5^{\circ} \mathrm{C}$ on the 12 th, and Cunderdin, Mullewa and Murchison all reached $47^{\circ} \mathrm{C}$.

In southeast Australia, temperatures peaked at $47.2^{\circ} \mathrm{C}$ at Keith West, in the Upper Southeast district of South Australia, on 14 January. The highest temperatures of the heatwave in Victoria and Tasmania also occurred on the $14 \mathrm{th} ; 46.5^{\circ} \mathrm{C}$ at Charlton and $40.2^{\circ} \mathrm{C}$ at Bushy Park respectively. Another notable reading on the 14 th was $38.6^{\circ} \mathrm{C}$ at

Scotts Peak, which equalled the highest temperature ever observed at any site in western Tasmania ${ }^{1}$.

Temperatures remained high for the following three days. $46^{\circ} \mathrm{C}$ was exceeded in Victoria on both the 15 th ( $46.2^{\circ} \mathrm{C}$ at Charlton) and the 17 th ( $46.3^{\circ} \mathrm{C}$ at Avalon). The 17th was also the hottest day of the heatwave in New South Wales, with $45.5^{\circ} \mathrm{C}$ at Hay Airport. Very hot conditions continued into the 18th in New South Wales and the far northeast of Victoria before temperatures in those regions returned closer to normal levels from the 19th.

Relatively few site records were set at locations with 40 or more years of data in southeast Australia (Table 1), with most locations failing to surpass the peak values reached during the 2009 heatwave. The most significant records were set in the southeast of South Australia on the 14th, and in and to the west of the Snowy Mountains in New South Wales on the 16 th. It was also notably warm at high-elevation locations in Tasmania on the 14th, with Mount Read $\left(30.4^{\circ} \mathrm{C}\right)$ and Mount Wellington (29.8 ${ }^{\circ} \mathrm{C}$ ) both reaching their highest temperatures on record (Mount Read equalled this record again on the 16th). A few records were also set in Western Australia in the first phase of the heatwave, including Perth's hottest night on record, $29.7^{\circ} \mathrm{C}$ on the 12 th.
In Adelaide, the temperature reached $45.1^{\circ} \mathrm{C}$ on the 14 th, the fourth-highest temperature on record for the city and the fifth occasion on which it has reached $45^{\circ} \mathrm{C}$. Three of those five occasions have been in the last five years (in 2009, 2013 and 2014). At Canberra, where there were three days of $40^{\circ} \mathrm{C}$ or above, nine of the thirteen recorded days of $40^{\circ} \mathrm{C}$ or above have occurred in the last eight years (one in 2007, three in 2009, two in 2013, two in 2014).
Melbourne's highest temperature peaked at $43.9^{\circ} \mathrm{C}$, on both the 16 th and 17 th. These values were the equal ninth-highest on record, while the minima of $28.6^{\circ} \mathrm{C}$ and $27.0^{\circ} \mathrm{C}$ on the 15th and 16 th rank third and sixth respectively. The daily mean temperature ${ }^{2}$ of $35.45^{\circ} \mathrm{C}$ on the 16 th was Melbourne's highest on record, just surpassing the $35.4^{\circ} \mathrm{C}$ observed on 30 January 2009. All four instances of daily mean temperature of $35^{\circ} \mathrm{C}$ or above in Melbourne have occurred since 2009, two in 2009 and two in 2014. The combined maximum and minimum temperature is an important measure of heatwave intensity, as high night temperatures exacerbate the impact of hot days.

It reached $45^{\circ} \mathrm{C}$ in Victoria on three days during the heatwave. There have now been 21 calendar days in the period from 2001-2014 when it has reached $45^{\circ} \mathrm{C}$ at one or more Victorian locations ( 1.5 days per year), compared with 13 days in the 44 years

[^0]( 0.3 days per year) from 1957 to 2000 (Figure 1) ${ }^{3}$. This is an approximately fivefold increase in the average annual frequency of such temperatures.

On a number of occasions during the heatwave, temperatures rose sharply for a period during the night, as a result of outflows from nearby thunderstorms. At Laverton on the night of $14-15$ January, temperatures rose to $38.6^{\circ} \mathrm{C}$ at 11.55 p.m., while in the early morning of 16 January, Bendigo reached $36.8^{\circ} \mathrm{C}$ at 4.37 a.m., and Longerenong $35.1^{\circ} \mathrm{C}$ at 6.00 a.m. Laverton's $37.4^{\circ} \mathrm{C}$ at midnight on the 15 th is the second-highest midnight temperature on record for any Victorian location, behind $37.5^{\circ} \mathrm{C}$ at Rutherglen on 8 February 2009, while Longerenong's $35.1^{\circ} \mathrm{C}$ on the 16th is the third-highest 6 a.m. temperature on record in Victoria, after readings of $35.6^{\circ} \mathrm{C}$ at Wilsons Promontory on 29 January 2009 and 12 January 2010.

Another notable feature of the heatwave was the very large diurnal temperature ranges recorded at some inland locations. Westmere, in western Victoria, had a minimum of $5.0^{\circ} \mathrm{C}$ and a maximum of $39.3^{\circ} \mathrm{C}$ on the $13 \mathrm{th} .34 .3^{\circ} \mathrm{C}$ is the largest diurnal temperature range on record at any Victorian site, surpassing $34.1^{\circ} \mathrm{C}\left(34.0^{\circ} \mathrm{C} /-0.1^{\circ} \mathrm{C}\right)$ at Fiskville (near Ballan) on 12 January 1957. On the 17th, Canberra ( $39.7^{\circ} \mathrm{C} / 11.2^{\circ} \mathrm{C}$ ) had its largest diurnal range on record ${ }^{4}, 28.5^{\circ} \mathrm{C}$, while Braidwood ( $38.3^{\circ} \mathrm{C} / 7.5^{\circ} \mathrm{C}$ ) and Goulburn Airport $\left(37.4^{\circ} \mathrm{C} / 6.9^{\circ} \mathrm{C}\right)$ had diurnal ranges in excess of $30^{\circ} \mathrm{C}$.

### 2.3 Extent and duration of the heatwave

The heatwave affected large parts of southeastern Australia (Figure 2), with maximum temperatures for the period $13-17$ January $12^{\circ} \mathrm{C}$ or more above normal in most of Victoria, most areas of South Australia within 200 kilometres of the coast, and parts of central Tasmania.

The main focus was in Victoria. In Victoria, the statewide average maximum temperature exceeded $41^{\circ} \mathrm{C}$ on four successive days from 14 to 17 January (Table 2), surpassing the record of three successive days set in 2009. The daily mean temperature exceeded $32^{\circ} \mathrm{C}$ on three successive days, also breaking a record set in 2009, while four successive days with daily means in excess of $30^{\circ} \mathrm{C}$ matched the 2009 record. (Before this heatwave, there had only been four days with statewide mean temperatures exceeding $32^{\circ} \mathrm{C}$, three in 2009 and one in 1959). Three consecutive days with statewide average minimum temperature exceeding $22^{\circ} \mathrm{C}$ broke the record of two

[^1]set in 1997 and 2009. While no individual days set records at a state level in Victoria, two days during the heatwave ranked in the ten highest on record for both maximum and minimum temperature (Table 2), while three days had mean temperatures ranking in the all-time top seven. As for days reaching $45^{\circ} \mathrm{C}$ at individual locations, the frequency of days with a statewide mean temperature of $30^{\circ} \mathrm{C}$ has increased markedly since 2001 (Figure 3).

The peak period of the southern Australian heatwave occurred at the same time as below-normal temperatures, associated with a monsoonal low, affected much of the Northern Territory and northern Western Australia, and hence nationally-averaged temperatures fell well short of those experienced in January 2013.

### 2.4 Consecutive days with temperatures above thresholds

The heatwave was notable for its duration. Although peak temperatures generally fell short of those experienced during the 2009 heatwave, it lasted for longer in some locations, particularly near the coasts of Victoria and South Australia.
Some records set for consecutive days with maximum or minimum temperature above thresholds are shown in Table 3. The majority of these records occurred in nearcoastal regions of South Australia and central and western Victoria, but there were also some in inland parts of Victoria and southern New South Wales, and in alpine areas.

Melbourne set records with four consecutive days of $41^{\circ} \mathrm{C}$ and above and two consecutive nights of $27^{\circ} \mathrm{C}$ and above, while Adelaide set a record with five consecutive days of $42^{\circ} \mathrm{C}$ and above. In both cases, the 2014 heatwave was less intense but longer than that of 2009 (when Melbourne and Adelaide had three and four consecutive days, respectively, of $43^{\circ} \mathrm{C}$ and above); conversely, it was more intense but shorter than that of 1908 (when the two cities had five and six consecutive days, respectively, of $40^{\circ} \mathrm{C}$ or above). Canberra also set a record with four consecutive days of $39^{\circ} \mathrm{C}$. A detailed set of historical heatwave records for various thresholds for all three cities is given in Table 4. The heatwave index used in the Bureau's heatwave forecasts reached its second-highest level on record for Melbourne, and its third-highest in Adelaide (in both cases the 2009 heatwave produced the highest value).
In general terms, the 2014 heatwave can be considered as broadly comparable for extended heat in coastal areas of Victoria and South Australia with those of 2009 and 1908, with the ranking of the three depending on the indicator used. In inland areas, while records were set locally, most locations fell short of benchmarks set in 2009 and
1939. It is difficult to make a full assessment of the 1908 heatwave as few stations in inland Victoria or New South Wales had data comparable with current standards ${ }^{5}$.

| 35 | 15 | 3-17/3/2008 | 6 | $\begin{aligned} & \text { 15-20/1/1908, 13- } \\ & 18 / 1 / 1981 \end{aligned}$ | 9 | 21-29/1/1947 |

Table 4. Maximum number of days with maximum temperature at or above thresholds at Adelaide, Melbourne and Canberra. Values which occurred during the 2014 heatwave are shown in bold.

## Further information

This statement is based on data available as of 19 January 2014. Some changes may occur as a result of late-arriving data or the Bureau's routine quality control procedures.

Temperature data prior to 1910 are generally not used for the purposes of this Statement due to the lack of standardisation of instrument shelters, making most pre-1910 observations not strictly comparable with more recent data. However, data which are known to have been measured in a Stevenson screen are included. This includes Melbourne data from 1 January 1908, and Adelaide data from 1 January 1887.

[^0]:    ${ }^{1}$ This equalled $38.6^{\circ} \mathrm{C}$ at Strahan on 15 February 1982.
    ${ }^{2}$ Daily mean temperature is calculated as the mean of the maximum and minimum temperature.

[^1]:    ${ }^{3} 1957$ is taken as the starting point as daily data prior to 1957 have not yet been digitised at a number of key locations (e.g. Ouyen, Horsham, Echuca), and hence this indicator would miss a number of days with temperatures above $45^{\circ} \mathrm{C}$ prior to 1957 .
    ${ }^{4}$ The previous record was $28.4^{\circ} \mathrm{C}$ on three separate occasions, most recently on 18 January 2013.

[^2]:    ${ }^{5}$ Stevenson screens had been installed at most South Australian stations, and at Melbourne and some other coastal Victorian stations, by January 1908, but most stations in inland areas of Victoria and southern New South Wales did not have Stevenson screens installed until later in 1908. Data from Mildura, where a Stevenson screen was installed in 1906, suggest that the 1908 heatwave was less significant there than the 1939, 2009 and 2014 heatwaves, with only one day over $44^{\circ} \mathrm{C}$
